ABSTRACT

The concentrations of heavy metals (Cu, Zn, Fe, Pb and Hg) were measured in the Muscles, liver, gills, kidney and gonad of fish species collected from Umrar Dam, Umaria in central India. The levels of heavy metals varied significantly among fish species and organs. Muscles possessed the lowest concentration of metals. The essential metals as Cu were accumulated mainly in liver and gonad, Zn accumulated mainly in Gills and Liver, Fe were accumulated in all organs with little bit fluctuation in concentration while Pb accumulated in gill, liver and gonad and Hg levels were below detectable limits. The concentration of metals in the present fish organs within the permissible limits given by WHO and FAO but in case of Pb these are higher than the limits. This is also noticeable that the concentration of metals is higher in summer seasons while lowest concentrations are found in winter. This study reveals that fishes found in this dam are not suitable for human consumption it may cause severe health hazard because of high concentration of lead.

INTRODUCTION

The pollution of the aquatic environment with heavy metals has become a worldwide problem in recent years, because they are indestructible and most of them have toxic effect on organisms [17].In the recent years, world consumption of fish has increased simultaneously with the growing concern of their nutritional and therapeutic benefits. In addition to its important source of protein, fish typically have rich contents of essential minerals, vitamins and unsaturated fatty acids[19].The American Heart Association recommended eating fish at least twice per week in order to reach the daily intake of omega-3 fatty acids. However, fish are relatively situated at the top of the aquatic food chain; therefore they normally can accumulate heavy metals from food, water and sediments.[09]

In the last few decades, the concentrations of the heavy metals in fish have been extensively studied in different parts of the world.[13]Most of these studies concentrated mainly on the heavy metals in the edible parts that is fish muscles however other studies reported the distribution of metals in different organs like the liver, kidney, hearts, gonads, bone, digestive tract, gills and brain. The content of toxic heavy metals in fish can counteract their beneficial effects and may cause many adverse effects on human health this may include serious threats like renal failure, liver damage, cardiovascular diseases and even death. [16, 18]

Heavy metals are implicated in neurological disorders especially in the foetus and in children, which can lead to behavioural changes and impaired performance in intelligent quotient (IQ) test[15].The quality of the ecosystem has been degrading due to agriculture and human activities. Fish is an important component of the human diet in many villages and cities in shahdol division of central India and Umrar Dam is the very enormous source of fish culture and transportation of fishes to different region of shahdol division and other places too, for this reason, the results obtained from the study would provide information on background levels of metals in the fish species of the river Umrar, contributing to the effective monitoring of both environmental quality and the health of organisms inhabiting the river ecosystem.

It is therefore very important for study to be conducted on the concentration of heavy metals in the tissues of fishes of river Umrar in Umrar dam at Umaria district in central India and check whether or not the concentration levels are within the permissible limits for human consumption in comparison to safety reference standards for the consumption of fish. Because in this area many people are dependent on fish as a food, especially fisher mans and it may cause severe health hazards.

MATERIALS AND METHODS

FISH SAMPLING

12 water samples and 24 commercial fish samples were used for study in three seasons of the year summer, winter and rainy, during two years (from 2015-16 to 2016-17) from every site. The collected species were *Labeo rohita, Rasbora daniconius and Ompak bimaculatus*. These fish species represent different biotopes and are economically important. Collected fish were immediately preserved in an ice box and transferred to the laboratory where they were classified, weighed, measured by total length and kept frozen at −20 °C until further analysis. The fish and water samples collected from the different sites and analyzed at laboratory. Atomic Absorption Spectrophotometer (AAS) was used for the determination of the heavy metals in the tissue and water samples.

DETERMINATION OF METAL CONCENTRATIONS

Preparation of subsamples and analysis were made for metal analysis, frozen fish were partially thawed and each fish was dissected using stainless steel instruments. Muscles, Liver, Gills, Kidney and Gonad were taken out and dehydrated it, in oven, composite samples of 2–5 g were used for subsequent analysis.

The samples were digested with ultra pure nitric acid at 100°C until the solution become clear. The solution was made up to known volume with deionized distilled water and analyzed for Cu, Zn, Pb, Fe and Hg using the Atomic Absorption Spectrophotometer (AAS model ELICO, SL-168) the obtained results were expressed as mg/kg.

STATISTICAL ANALYSIS

Results were generally expressed as mean ± standard deviation and one way ANOVA test was used to compare the data among seasons at the level of 0.05.

OBSERVATIONS

Concentrations of heavy metals (Cu, Zn, Pb, Fe and Hg) in the muscles, liver, gill, kidney and gonad of fish collected from the different sites of Umrar Dam.

As shown in Table-01, the contamination levels of these five metals were high in tissues. Specially, the concentration of Pb exceeding, FAO and WHO target values. Consumption of water as well as fish may create health problems related with Pb contamination may occur in human beings.

The accumulation of metals in a single species showed significant inter-specific variations in all metals. However it can be noticed that, different organs exhibited different patterns in metals accumulation. In other words, no single type of fish showed the highest metals in all

organs. Therefore, concentrations of metals between species were analyzed in single organ; all results showed significant variations between species. Furthermore, some fish from the same species collected from different sites also significantly accumulated different concentrations of metals. Variations of metals distribution in the studied fish can be summarized as the following:

Table-I:- Table showing mean (±SD) concentrations of heavy metals (mg/kg) in some organs of fish species collected from Umrar Dam.

Copper (Cu)

The copper concentration in the tissues of *Labeo rohita* is highest in the summer season in about all organs taken for observation .Copper concentrations are reached the highest level in kidney in summer (3.440±0.005) whereas lowest concentrations are found in muscles in rainy season (0.021±0.001).In *Rasbora daniconius* copper concentration reached the highest in kidney in summer (3.241±0.002) and lowest are found in muscle in rainy season (0.201±0.000) and in *Ompak*

bimaculatus highest concentration is in kidney (4.001±0.001)in summer whereas lowest is in muscles in rainy season (0.122±0.001). Copper concentrations varied highly significantly (P<0.001) from season to season in organs of all experimental fishes.

Zinc (Zn)

The Zinc concentration in the tissues of *Labeo rohita* is highest in summer whereas lowest concentrations are found in winter. Zn concentrations are reached the highest level in gills in summer (2.873±0.016) whereas lowest concentrations are found in muscles in rainy season (0.043±0.001).Zn concentrations varied highly significantly (P=0.001) from season to season in organs of *Labeo rohita*.In *Rasbora daniconius* Zn concentration reached the highest in gills in summer (0.194±0.000) and lowest are found in Kidney in winter season (2.883±0.001). Zn concentrations varied highly significantly (P<0.001) from season to season in organs of *Rasbora daniconius* and in *Ompak bimaculatus* highest concentration is in gills (4.001±0.001) in summer whereas lowest is in liver in rainy and winter seasons (0.200±0.001). Zn concentrations varied highly significantly (P<0.001) from season to season in organs of *Ompak bimaculatus.*

Iron (Fe)

The Fe concentration in the tissues of *Labeo rohita* is highest in summer whereas lowest concentrations are found in winter. Fe concentrations are reached the highest level in gonad in summer (0.903±0.003) whereas lowest concentrations are found in gills in rainy season (0.202±0.001).Fe concentrations varied highly significantly (P<0.001) from season to season in organs of *Labeo rohita*. In *Rasbora daniconius* Fe concentration reached the highest in gonad in summer (2.886±0.003) and lowest are found in gills in rainy season (0.201±0.001). Fe concentrations varied highly significantly (P<0.001) from season to season in organs of *Rasbora daniconius* and in *Ompak bimaculatus* highest concentration is in gonad (2.738±0.002) in summer whereas lowest is in muscle in rainy seasons (0.220±0.002). Fe concentrations varied significantly (P=0.05) from season to season in organs of *Ompak bimaculatus.*

Lead (Pb)

The Pb concentration in the tissues of *Labeo rohita* is highest in summer whereas lowest concentrations are found in winter. Fe concentrations are reached the highest level in gills in summer (3.081±0.000) whereas lowest concentrations are found in kidney in summer season (0.043±0.000).Pb concentrations varied highly significantly (P<0.001) from season to season in organs of *Labeo rohita*. In *Rasbora daniconius* Pb concentration reached the highest in gills in

summer (4.832±0.000) and lowest are found in kidney in winter season (0.725±0.000). Pb concentrations varied highly significantly (P<0.001) from season to season in organs of *Rasbora daniconius* and in *Ompak bimaculatus* highest concentration is in gonad (3.855±0.001) in summer whereas lowest is in kidney in winter seasons (0.789±0.000). Pb concentrations varied highly significantly (P<0.001) from season to season in organs of *Ompak bimaculatus.*

DISCUSSIONS

Knowledge of heavy metal concentrations in fish is important for both human consumption and nature management in this study; we examined metals in tissue of experimental fishes to evaluate heavy metal concentrations in Umrar dam. It is also aimed to investigate whether metal concentrations varied seasonally in the study.

Present study showed the lowest concentration of metals in muscle. The essential metals as Cu were accumulated mainly in liver, kidney and gonad, Zn accumulated mainly in Gills and Liver, Fe were accumulated in all organs with little bit fluctuation in concentration and Pb were accumulated mainly in gills and gonad.

The accumulation of metals in liver is probably linked to its role in metabolism[23] high levels of Cu and Zn in hepatic tissues are usually related to a natural binding proteins such as metallothioneins[11] which act as an essential metal store as Zn and Cu to fulfil enzymatic and other metabolic demands[22] while Fe tends to accumulate in hepatic tissues due to the physiological role of the liver in blood cells and haemoglobin synthesis[11].On the other hand, the liver also showed high levels of non-essential metals such as Pb to displace the normally metallothioneins associated metals in hepatic tissues[02].previous studies also show similar trends to accumulate high level of essential and non-essential metals in liver cells in fishes.[23,07,03,12,06]

Presence of these metals in gills shows that gills are main route of metal ion exchange from water [20] as they have large surface area and facilitate rapid diffusion of toxic metals [05].Therefore it is suggested that metals accumulated in gills are mainly concentrated from water specially Pb and Zn, previous studies also show the similar things as[14,04,01,20,07.]

In present study highest concentrations of metals are found in summer season whereas lowest concentrations are in rainy and winter seasons. The increase of heavy metal levels in summer and winter could be related to increasing physiological activity of fish during summer, primarily caused by the increasing water temperature and decrease in water level because of agricultural activities and domestic activities or high temperature as well. For all seasons we found Cu, Zn and Fe are under the limits of WHO, FAO, FSAI and FSSAI while Pb concentrations are higher than the permissible limits.

It is well known that muscles are not active site for metal biotransformation and accumulation[08] but in polluted aquatic habitats the concentration of metals in fish muscles may exceed the permissible limits for human consumption and imply severe health threats.

CONCLUSIONS

The concentration of metals in the present fish organs within the permissible limits given by WHO and FAO but in case of Pb these are higher than the limits. So health risk analysis of heavy metals in the edible part (muscle) of the fish indicated safe levels for human consumption and concentrations in the muscles are generally accepted by the international legislation limits however, whole fish with all organs specially small size fishes and the ovary is consumed by many people's of this region so study reveals that fishes found in this dam are not suitable for human consumption it may cause severe health threats.
