ABSTRACT

Nerve conduction studies are valuable aid to investigate and quantify the physiological activity of peripheral nerves. These include measurement of sensory and motor conduction velocities and latencies of peripheral nerves. These nerve conduction parameters may be affected by anthropometric factors like age, sex, height, weight, temperature and Body mass index. So during nerve conduction studies these factors should be taken into consideration. Majority of the available literature mentioning effects of age, height, Body mass index, temperature and gender on latency of nerve conduction measures have been referred in the present study.

KEYWORDS: Nerve conduction study, Latency, Physiological factors, Electrodiagnosis, Age, Gender, and Height were used.

INTRODUCTION

Nerve conduction study is a part of electro diagnostic procedure that helps in establishing the type and extent of abnormality of nerve. It assesses peripheral motor and sensory functions by recording the evoked response to electrical stimulation of peripheral nerves. These enable the clinicians to differentiate the two major groups of peripheral disease—demyelination and axonal degeneration. These also help in localizing site of lesion.

Physiological factors such as age, temperature, height and gender are known to affect the NCV. It is stated that fixing absolute thresholds without adjustments for age, sex, temperature and height may result in false positive and false negative results. In human, investigators have reported different values for different physiological factors. So, the following review is conducted to know how different factors affect the parameters of the nerve conduction study mainly the latency.

METHODOLOGY

The articles included:

- Were published either in year 2000 or after that
- Included the effect of physiological factors on latency of nerve conduction study,
- Included effect of physiological factors on both motor and sensory nerves

**CONCLUSION**

- Effect of age on latency
It can be concluded that there is strong evidence supporting that as age increases motor latency of median, ulnar, and tibial nerve increases. There is insufficient evidence about the effect of age on radial and peroneal nerve.

- **Effect of gender on latency**
  There is strong evidence that motor latency of median, ulnar and tibial nerves are longer in male compared to female. There is also significant change observed in sensory latency of median and ulnar nerves in response to gender showing more in males compared to females. There is no evidence of effect of gender on radial, peroneal and sural nerves.

- **Effect of height on latency**
  There is weak evidence supporting the effect of height on motor and sensory latency of median, ulnar, tibial and peroneal nerve suggestive positive correlation with height. There is no evidence for effect of height on radial and sural nerves.

- **Effect of BMI on latency**
  There is insufficient evidence about the effect of BMI on motor and sensory latency showing there is prolongation of latency with increasing BMI in median, ulnar, radial, and tibial except peroneal nerves.

- **Effect of temperature on latency**
  There is insufficient evidence about the effect of temperature on motor and sensory latency showing that latency increases with decrease in temperature.

**ACKNOWLEDGEMENT**

I would like to thank my parents, Guide, senior and colleagues for their support and guidance.

**CONFLICT OF INTEREST**

There was no personal or institutional conflict of interest for this study.

**SOURCE OF FUNDING**

No fund was needed.
